

Extraction
of $\tilde{\tau}_1$ mass and τ -polarization
in 2-body $\tilde{\chi}_2$ decays

Till Nattermann,
Peter Wienemann
Carolin Zender

- Introduction
- Endpoint determination with “low” integrated luminosity ($<10 \text{ fb}^{-1}$)
- Endpoint and polarization measurement with “high” integrated luminosity (several 10 fb^{-1})
- Conclusions
- Discussion

\star $BR(\chi_2^0 \rightarrow e^+ e^- \chi_1^0) \approx BR(\chi_2^0 \rightarrow \mu^+ \mu^- \chi_1^0) \approx 0.1 * BR(\chi_2^0 \rightarrow \tau^+ \tau^- \chi_1^0)$ for SU3
 \rightarrow more τ than e, μ due to R,L-mixing

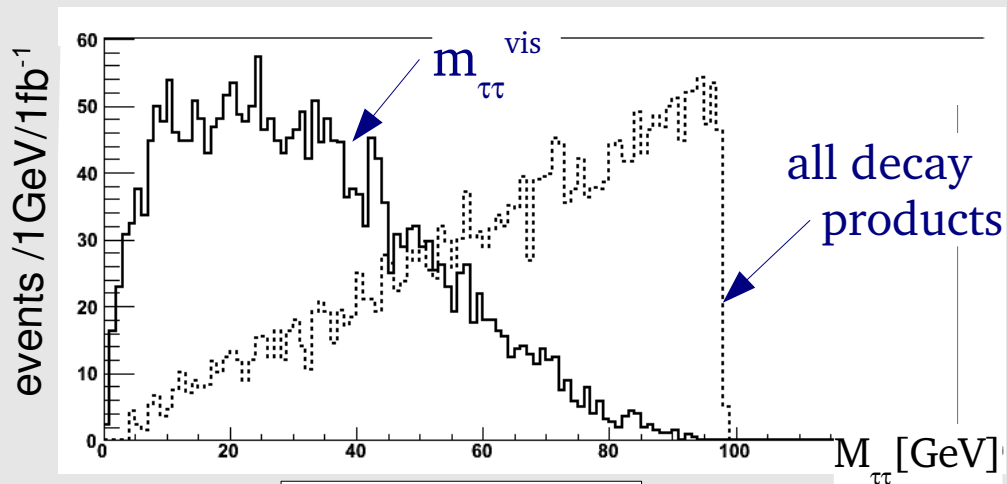

what kind of SUSY are we dealing with?

Ditau mass spectrum holds information about stau mass and mixing angle:

- \star Endpoint of $m_{\tau\tau}$ spectrum: $m_{\tau\tau}^{max} = \sqrt{\frac{(m(\tilde{\chi}_2^0)^2 - m(\tilde{\tau}_1)^2) \cdot (m(\tilde{\tau}_1)^2 - m(\tilde{\chi}_1^0)^2)}{(m(\tilde{\tau}_1)^2)}$
- \rightarrow if $m(\tilde{\chi}_{1,2}^0)$ known $\rightarrow m(\tilde{\tau}_1)$
- \star Sum of tau polarizations \rightarrow stau mixing angle

- ★ LSP not detected
- no mass peak, kinematic endpoint
- ★ $m_{\tau\tau}^{\text{vis}}$: sharp edge washed out due to escaping ν
- ★ little statistics left at edge
- need to approximate shape

Technicalities for ATLAS people:
 all results obtained with
 athena rel. 12 and
 TauRec or
 ATLFAST TauRec parameterization

generator level

★ **SU3:** $m(\tilde{\tau}_2) > m(\tilde{\chi}_1^0)$

→ only decays via $\tilde{\tau}_1$

SU3: mSUGRA bulk region point

$m_0 = 100 \text{ GeV}$ $\tan\beta = 6$

$m_{1/2} = 300 \text{ GeV}$ $\text{sgn}\mu = +$

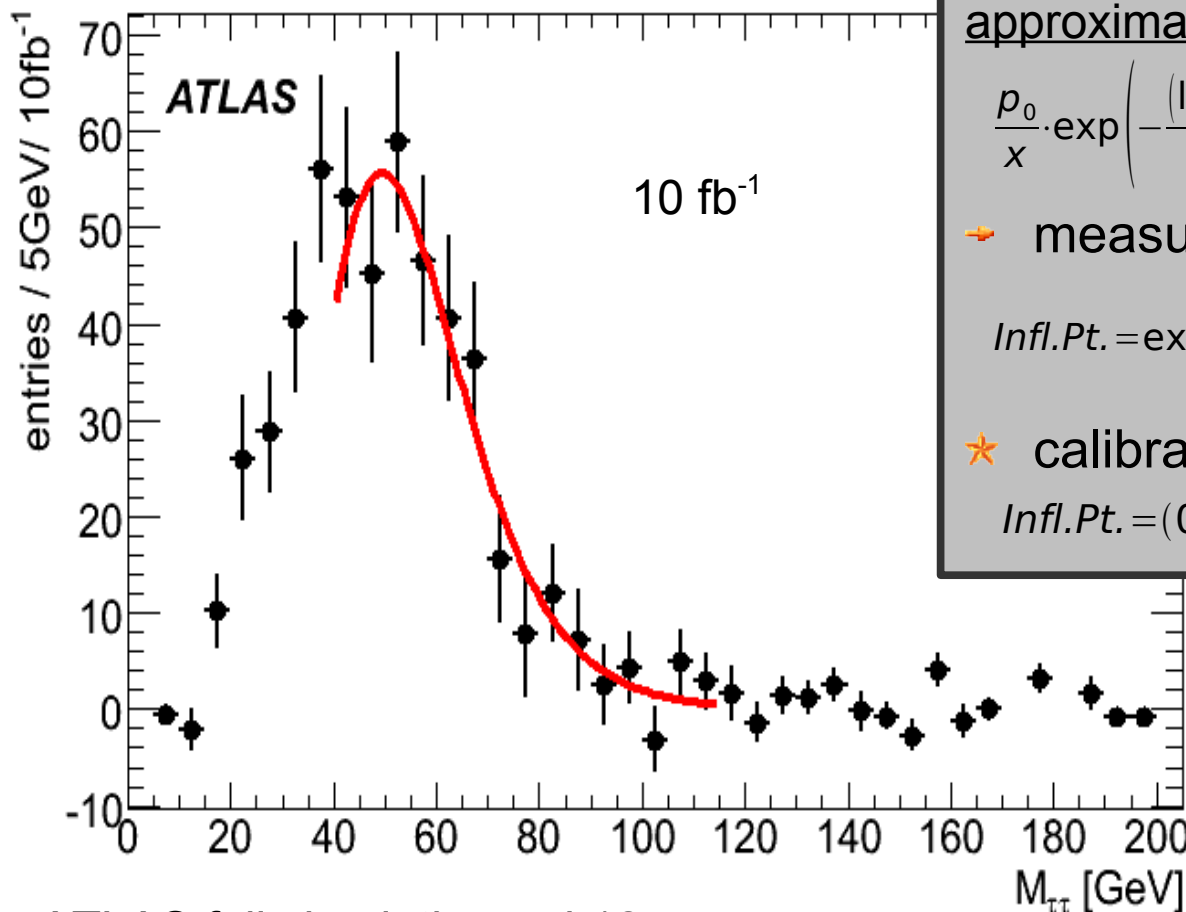

$A_0 = -300 \text{ GeV}$

selection cuts:

- $p_T^{\text{miss}} > 230 \text{ GeV}$
- 4 Jets: $p_T > 40 \text{ GeV}$
- 3 Jets: $p_T > 50 \text{ GeV}$
- 1 Jet: $p_T > 220 \text{ GeV}$
- $\Delta R(\tau\tau) < 2$
- OS-SS

ATLAS full simulation, rel.12

ATLAS full simulation, rel.12

approximate shape:

$$\frac{p_0}{x} \cdot \exp\left(-\frac{(\ln(x - p_1))^2}{2p_2^2}\right)$$

→ measure inflection point:

$$Infl.Pt. = \exp\left(\frac{-1}{2} p_2^2 \left(3 - \sqrt{\left(1 + \frac{4}{p_2^2}\right)}\right) + p_1\right)$$

★ calibration done with ATLFAST:

$$Infl.Pt. = (0.47 \pm 0.02) m_{\tau\tau}^{max} + (15 \pm 2) GeV$$

→ measured endpoint:

(theory: **99 GeV**)

103 ± 5^{stat} ± 4.5^{syst*} GeV

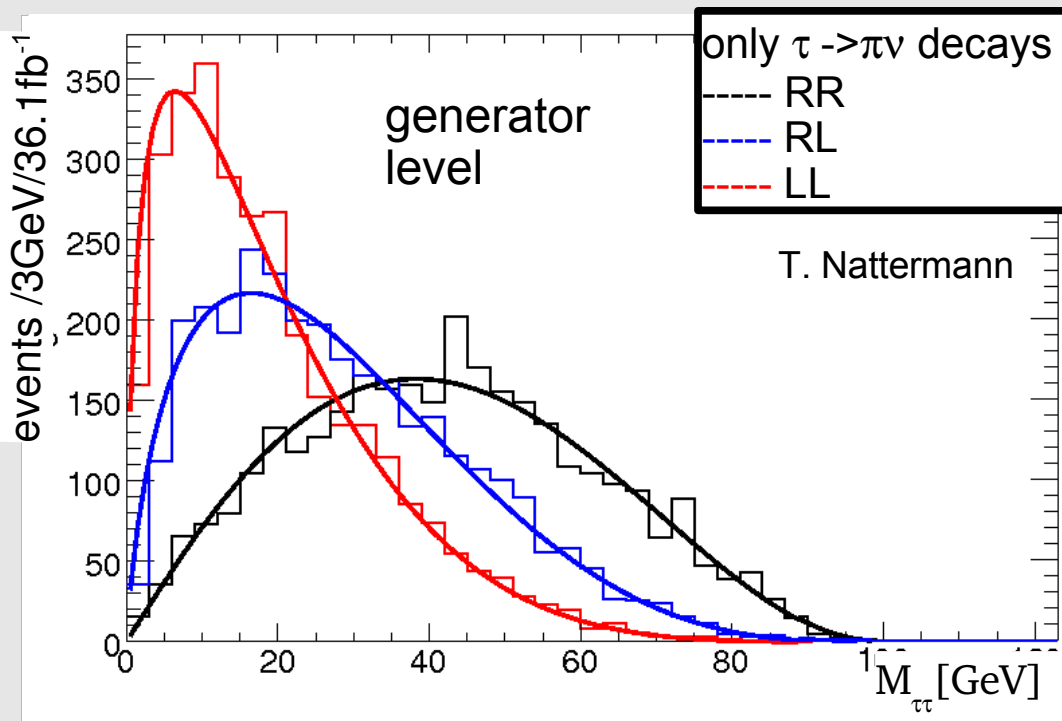

for 10 fb⁻¹

* syst. error: fast simulation

single pion decay:

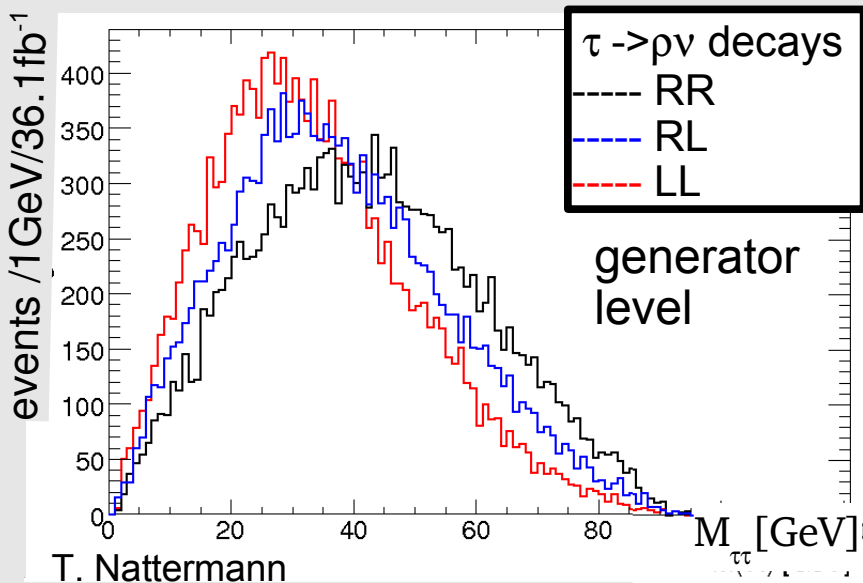

- ◆ angular momentum / momentum conservation + helicity of neutrino
- pion momentum direction determined by tau charge and helicity
- pion boosted (anti)parallel to tau momentum direction

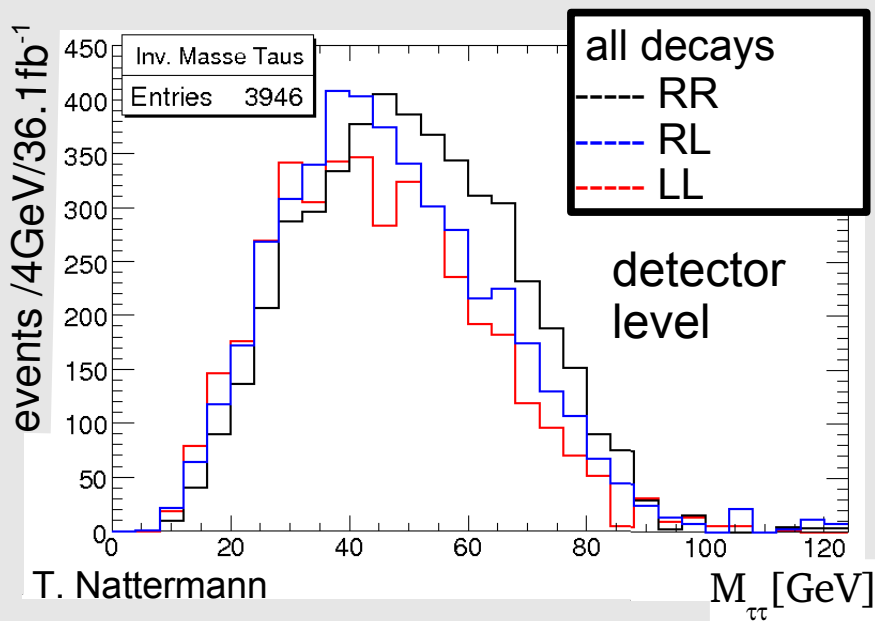

- shape of mass spectrum depends on tau polarization
- inflection point shifted

- ★ ρ/a_1 : same (opp.) momentum direction as π for long. (transv.) meson
- ◆ ρ : longitudinal share bigger than transversal
- ◆ a_1 : longitudinal and transversal share equal \rightarrow mass spectrum not shifted

♦ detector effects: ATLFAST (fast simulation)

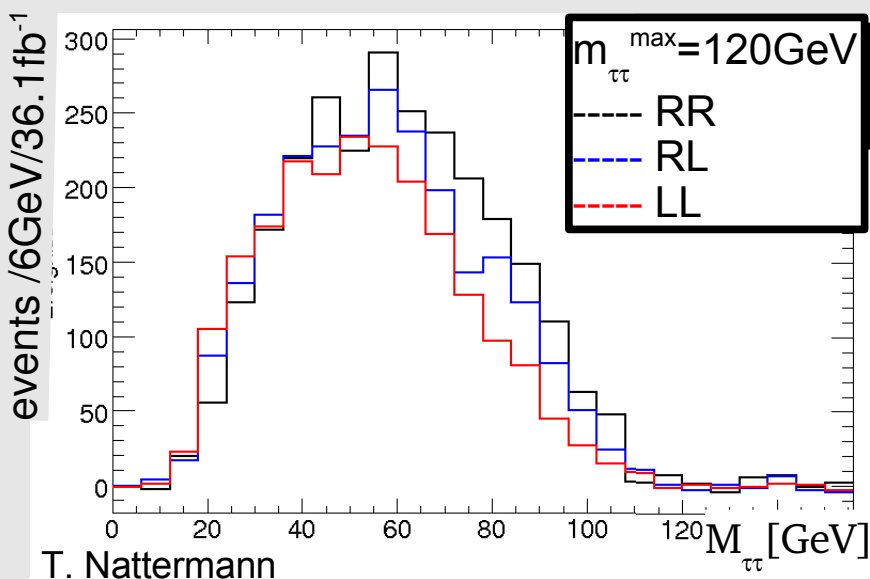

- shape deformed by low tau reconstruction efficiency at low p_T
- reduced shape information, rising edge determined by τ ID

- shift in trailing edge affects inflection point but not endpoint
- additional uncertainty on calibration showed before
- add. error on endpoint measurement: $\pm 3.5^{(pol)} \text{ GeV}$

- ★ to measure both endpoint and polarization: disentangle mass and polarization effects
- ➔ search traits with max. different sensitivity to mass / polarization:

polarization effect: fixed masses

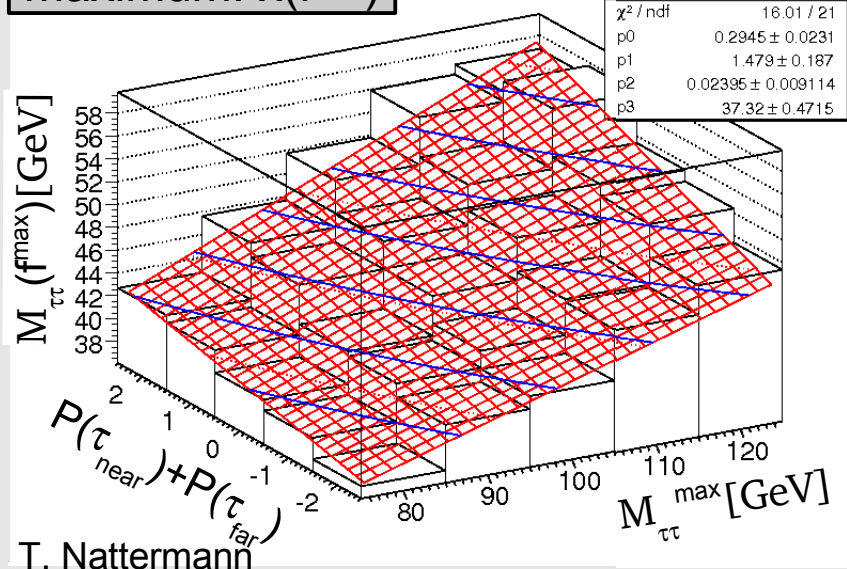

mass effect: fixed polarization

- ➔ max. difference close to maximum
- ➔ max. difference at high $m_{\tau\tau}$
- ➔ traits for calibration: maximum plus position of $0.1 \cdot \text{maximum}$

★ **Calibration:** measure $x(f^{\max})$, $x(0.1 \cdot f^{\max})$ with 1dim gauss fit: $f(x) = p_0 \cdot \exp\left(-\frac{(p_1 - x)^2}{2p_2^2}\right)$

maximum: $x(f^{\max})$

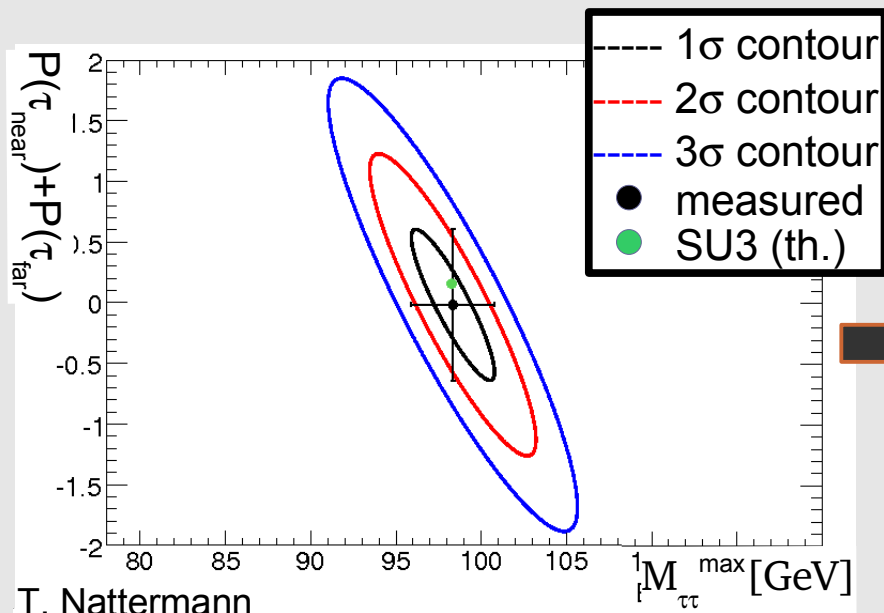

$x(0.1 \cdot f^{\max})$

- ★ 2dim fit function: $g(P, m) = p_0 P + p_1 m + p_1 P m + p_3$
- equipotential line from each of the two observables
- determine intersection in endpoint-polarization plane

★ measured SU3 values:

*systematic error included

$$m_{\tau\tau}^{\max} = (98.3 \pm 2.5^*) \text{ GeV}$$

$$P(\tau\tau) = P(\tau_{\text{near}}) + P(\tau_{\text{far}})$$

$$= (-0.02 \pm 0.6^*) \text{ GeV}$$

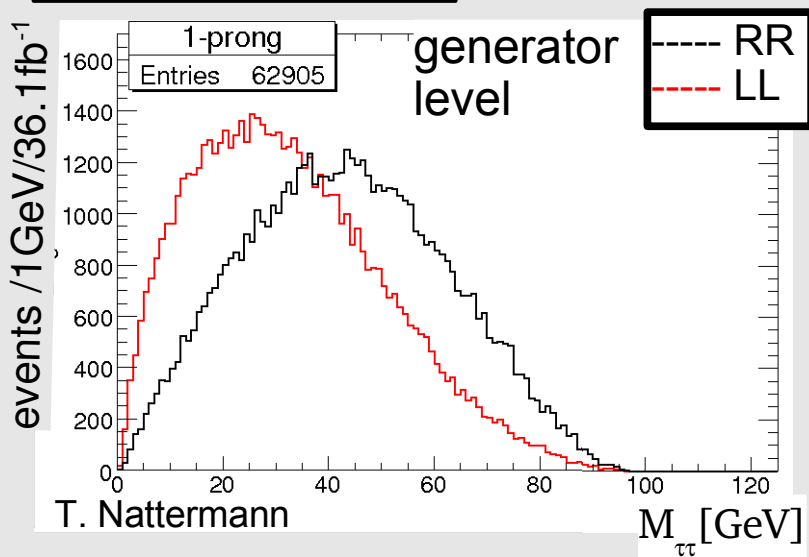

for 36 fb⁻¹

theory: $m_{\tau\tau}^{\max} = 99 \text{ GeV}$
 $P(\tau\tau) = +0.08$

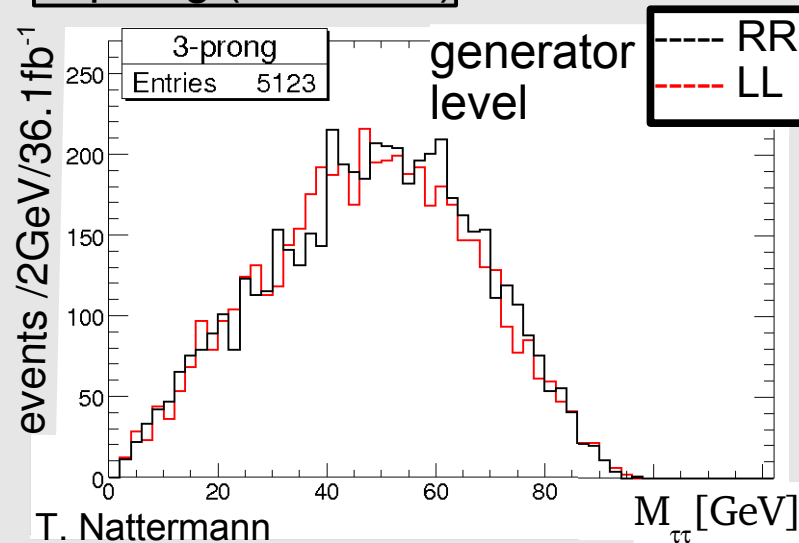

★ Can results be improved by separation of different tau decay modes?
remember: a₁ decays not affected by polarization effects

- ♦ separation of 1prong and 3prong decays:
 3p dominated by a_1 ($\sim 2/3$) and “others” (=not ρ, π, a_1) \rightarrow independent of polarization

1 prong (both taus)

3 prong (both taus)

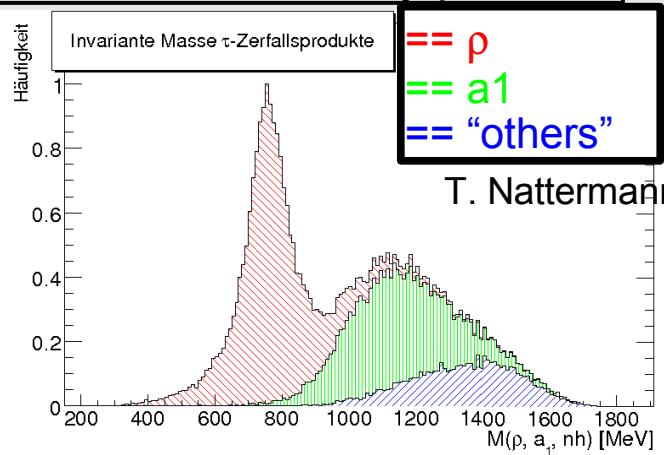

but: only 5% of double-hadronic decays are double-3prong
 + some a_1 also decay 1prong

\rightarrow on detector level and after selection cuts, not enough double-3prongs for endpoint determination

♦ use invariant mass of single tau decay products:

Inv. Mass of tau decay products

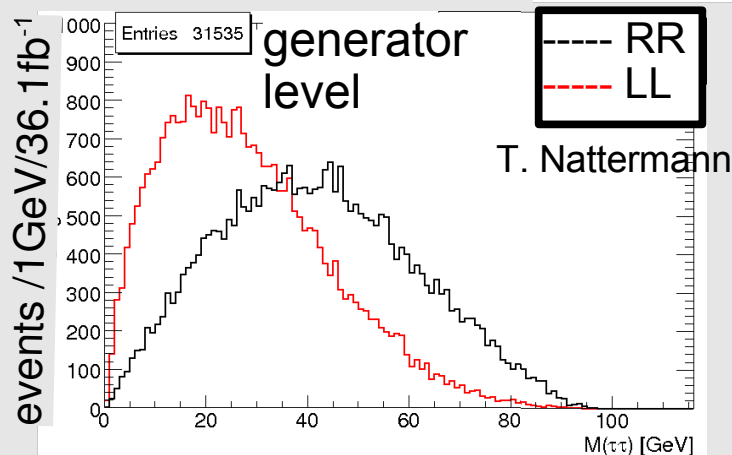

but: need to reconstruct all decay products correctly

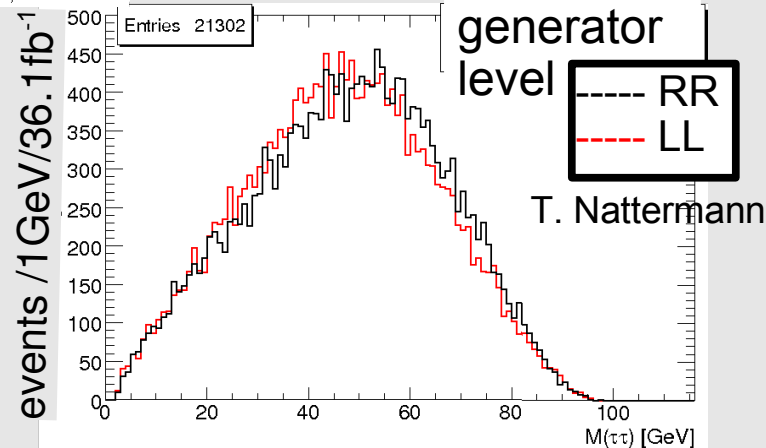

- currently not possible
- also not in ATLFAST

generator level

$p_\mu p^\mu < 900 \text{ MeV}$

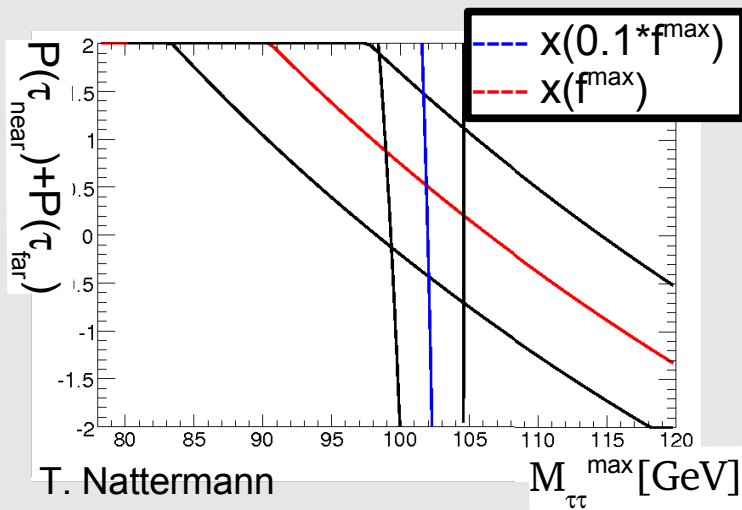

$p_\mu p^\mu > 900 \text{ MeV}$

...but how much **could** be gained by such a separation?

- ◆ take reconstructed taus + information about decay mode from truth-match
- ◆ fake taus: probability according to branching fraction
- ➔ 6 separate calibrations:
 - 2/1/0 taus decayed in polarization sensitive mode
 - x 2 observables

preliminary

- ★ 0.1*maximum: from polarization **independent** spectrum (21%)
- ★ maximum: from polarization **dependent** spectrum (50%)
- ➔ less parallel, intersection steeper
- ➔ error bands broader due to statistics loss
- ➔ measurement of $m_{\tau\tau}^{\max}$ and $\rho(\tau\tau)$ could not be improved
- ➔ but: used only 2 out of 6 calibrations
-> repeat with full information: under study

- ◆ $m_{\tau\tau}^{\max}$ and sum of tau polarizations $P(\tau\tau)$ provide important information for SUSY parameter determination

- ◆ can be measured accurately:

for SU3 ($m_{\tau\tau}^{\max} = 99 \text{ GeV}$, $P(\tau\tau) = +0.08$) our methods yield

$$m_{\tau\tau}^{\max} = (103 \pm 5^{\text{stat}} \pm 4.5^{\text{syst}} \pm 3.5^{\text{pol}}) \text{ GeV for } 10 \text{ fb}^{-1}$$

and

$$m_{\tau\tau}^{\max} = (98.3 \pm 2.5) \text{ GeV,}$$

$$P(\tau\tau) = (-0.02 \pm 0.6) \text{ GeV for } 36 \text{ fb}^{-1}$$

- ◆ these results could *principally* be improved by use of tau decay information: under study
- ◆ an accurate separation of tau decay modes would be desirable for high luminosity studies

backup

- 1 trigger
- 2 efficiency (SU3)
- 3 efficiency for SU3 events passing cuts:
 $met > 230\text{GeV}$, jet pts(220/50/50/40), $2N_{\tau} DR < 2$
- 3b efficiency for SU3 events passing cuts:
 $met > 230\text{GeV}$, jet pts(220/50/50/40), $N_{\tau} \geq 2$

tau trigger results also not compatible to numbers given for SU3 in Tau Trigger CSC Note
